## Abstract

Rodriguez Villegas expressed the Mahler measure of a polynomial in terms of an infinite series. Lück's combinatorial  $L^2$ -torsion leads to similar series expressions for the Gromov norm of a knot complement.

In this note we show that those formulae yield interesting power series expansions for the logarithm function. This generalizes an infinite series of Lehmer for the natural logarithm of 4.

## 1 The abelian case: the Mahler measure

For a Laurent polynomial  $P$  in the group ring  $\mathbb{C}[\mathbb{Z}^r]$  let the conjugate  $P^*$  be defined by sending every  $g \in \mathbb{Z}^r$  to  $g^{-1}$  and every coefficient  $a_g$  to its complex conjugate  $\overline{a_g}$ .

The (logarithmic) Mahler measure (see e.g. [EW99]) of  $P$  is given by:

$$m(P) = \int_0^1 \cdots \int_0^1 \ln |P(e^{2\pi i t_1}, \dots, e^{2\pi i t_r})| dt_1 \cdots dt_r.$$

The following theorem is due to Rodriguez Villegas [RV99]. Independently, it also appears in the study of the combinatorial  $L^2$ -torsion due to Lück. Further discussions are given in [DL08]. We include a proof along the lines of [RV99] for completeness.

**Theorem 1.1** ([RV99], see also [Lüc02, Den06]). *For  $k$  greater than the  $l^1$ -norm of the coefficients of  $P$  we have*

$$2m(P) = m(P P^*) = 2 \ln(k) - \sum_{n=1}^{\infty} \frac{1}{n} \left[ \left( 1 - \frac{1}{k^2} P P^* \right)_0^n \right], \quad (1)$$

where  $[P]_0$  denotes the constant coefficient of the Laurent polynomial  $P$ .

*Proof.* Since

$$PP^* = k^2 \left( 1 - \left( 1 - \frac{1}{k^2} PP^* \right) \right)$$

we have

$$m(PP^*) = 2 \ln(k) + m \left( 1 - \left( 1 - \frac{1}{k^2} PP^* \right) \right).$$

Set  $Q := 1 - \frac{1}{k^2} PP^*$  and let

$$\begin{aligned} u(Q, x) &:= \int_0^1 \cdots \int_0^1 \frac{1}{1 - xQ(e^{2\pi it_1}, \dots, e^{2\pi it_r})} dt_1 \cdots dt_r \\ &= \sum_{n=0}^{\infty} x^n \int_0^1 \cdots \int_0^1 Q(e^{2\pi it_1}, \dots, e^{2\pi it_r})^n dt_1 \cdots dt_r \\ &= \sum_{n=0}^{\infty} x^n [Q^n]_0 \end{aligned}$$

The choice of  $k$  ensures convergence.

Now

$$\begin{aligned} m(1 - xQ) &= \int_0^1 \cdots \int_0^1 \ln |1 - Q(e^{2\pi it_1}, \dots, e^{2\pi it_r})| dt_1 \cdots dt_r \\ &= \int_0^1 \cdots \int_0^1 \ln(1 - Q(e^{2\pi it_1}, \dots, e^{2\pi it_r})) dt_1 \cdots dt_r \\ &= - \int_0^x (u(Q, z) - 1) \frac{dz}{z} \\ &= - \sum_{n=1}^{\infty} \frac{1}{n} x^n [Q^n]_0 \end{aligned}$$

setting  $x := 1$  yields the result. □

## 2 A power series for the natural logarithm

Here we study an application of Equation (1) which leads to an interesting identity. For the polynomial  $1 + a$  the right-hand side of Equation (1) yields:

$$\begin{aligned} &2 \ln(k) - \sum_{n \geq 1} \frac{1}{n} \operatorname{tr}_{\text{CG}} \left( 1 - \frac{1}{k^2} (1 + a)(1 + a^{-1}) \right)^n \tag{2} \\ &= 2 \ln(k) - \sum_{n \geq 1} \frac{1}{n} \operatorname{tr}_{\text{CG}} \left( \sum_{j=0}^n \binom{n}{j} \left( -\frac{1}{k^2} \right)^j (2 + a + a^{-1})^j \right) \end{aligned}$$

Hence, with a formal  $\sqrt{a}$ :

$$\begin{aligned} &= 2 \ln(k) - \sum_{n \geq 1} \frac{1}{n} \text{tr}_{CG} \left( \sum_{j=0}^n \binom{n}{j} \left(-\frac{1}{k^2}\right)^j \left(\sqrt{a} + \frac{1}{\sqrt{a}}\right)^{2j} \right) \\ &= 2 \ln(k) - \sum_{n \geq 1} \frac{1}{n} \sum_{j=0}^n \binom{n}{j} \left(-\frac{1}{k^2}\right)^j \binom{2j}{j} \end{aligned}$$

On the other hand we know by Theorem 1.1 that the right-hand side of Equation (1) equals the logarithm of the Mahler measure of  $(1 + a)$  which is 0. This shows:

**Theorem 2.1.** *For  $x \geq 4$  a power series for the logarithm is given by:*

$$\ln x = \sum_{n \geq 1} \sum_{j=0}^n \frac{1}{n} \binom{n}{j} \binom{2j}{j} \left(-\frac{1}{x}\right)^j$$

The case  $x = 4$  is somewhat special. Equation (2) at  $x = k^2 = 4$  equals:

$$\begin{aligned} &2 \ln 2 - \sum_{n \geq 1} \frac{1}{n} \text{tr}_{CG} \left( \frac{a - 2 + a^{-1}}{-4} \right)^n \\ &= 2 \ln 2 - \sum_{n \geq 1} \frac{1}{n} \text{tr}_{CG} \left( (-1)^n \frac{(\sqrt{a} - 1/\sqrt{a})^{2n}}{4^n} \right) \\ &= 2 \ln 2 - \sum_{n \geq 1} \frac{1}{n} \binom{2n}{n} \frac{1}{4^n} \end{aligned}$$

Thus, we recover an identity which is well-known to Mathematica [Wol99] and was derived by Lehmer in [Leh85]:

$$\ln 4 = \sum_{n=1}^{\infty} \frac{1}{n} \binom{2n}{n} \frac{1}{4^n}. \tag{3}$$

The function also converges at  $x = k^2 = 2$  and yields:

$$\ln 2 = \frac{1}{2} \ln 4 = \sum_{n=1}^{\infty} \frac{1}{2n} \binom{2n}{n} \frac{1}{4^n}.$$

## 2.1 A generating function

It is interesting to look at the series for the natural logarithm in Theorem 2.1 from a generating function point of view:

Let

$$f_n(y) = \sum_{j=0}^n \frac{1}{n} \binom{n}{j} \binom{2j}{j} y^j$$

and

$$F(x, y) = \sum_{n \geq 1} f_n(y)x^n$$

its generating function.

Similar to Example 5, Section 4.3 in [Wil94] we have:

$$\begin{aligned} F(x, y) &= \sum_{n \geq 1} \sum_{j=1}^n \frac{1}{n} \binom{n}{j} \binom{2j}{j} y^j x^n + \sum_{n \geq 1} \frac{1}{n} x^n \\ &= \sum_{j=1}^{\infty} \binom{2j}{j} y^j \sum_{n=j}^{\infty} \frac{1}{n} \binom{n}{j} x^n - \ln(1-x) \\ &= \sum_{j=1}^{\infty} \binom{2j}{j} y^j \frac{1}{j} \left( \frac{x}{1-x} \right)^j - \ln(1-x) \\ &= \sum_{j=1}^{\infty} \binom{2j}{j} \frac{1}{j} \left( \frac{xy}{1-x} \right)^j - \ln(1-x) \\ &= \ln 4 - 2 \ln \left( 1 + \sqrt{1 - 4 \frac{xy}{1-x}} \right) - \ln(1-x) \\ &= \ln 4 - 2 \ln(\sqrt{1-x} + \sqrt{1-x-4xy}) \end{aligned}$$

Here we make use of the identity [Leh85]

$$\sum_{j=1}^{\infty} \frac{1}{j} \binom{2j}{j} z^j = 2 \log \left( \frac{1 - \sqrt{1-4z}}{2z} \right)$$

## 2.2 Triple Sum Series

By working with the polynomials  $1 + a + a^2 + \dots + a^n$  in Equation (1) one readily obtains other infinite series for the logarithm. For example if  $1 + a + a^2$  and we see for  $k \geq \sqrt{3}$ :

$$\begin{aligned} 2 \ln k &= \sum_{n \geq 1} \frac{1}{n} \text{tr}_{\text{CG}} \left( 1 - \frac{1}{k^2} (1 + a + a^2)(1 + a^{-1} + a^{-2}) \right)^n \\ &= \sum_{n \geq 1} \frac{1}{n} \text{tr}_{\text{CG}} \left( \sum_{j=0}^n \binom{n}{j} \left( -\frac{1}{k^2} \right)^j (a^{-1} + 1 + a)^{2j} \right) \\ &= \sum_{n \geq 1} \frac{1}{n} \sum_{j=0}^n \binom{n}{j} \left( -\frac{1}{k^2} \right)^j \sum_{l=0}^j \binom{2j}{2j-2l, l, l}, \end{aligned}$$

where the terms in the inner most sum are multinomial coefficients.

### 3 Motivations: $L^2$ -torsion of knot complements

To generalize the setting and to explain our original motivation we need to fix some notations. Let  $K$  be a knot and

$$G = \pi_1(S^3 - K) = \langle x_1, \dots, x_g | r_1, \dots, r_{g-1} \rangle$$

be a presentation of the fundamental group of the knot complement. For a square matrix  $M$  with entries in  $\mathbb{C}G$  the trace  $\text{tr}_{\mathbb{C}G}(M)$  denotes the coefficient of the unit element in the sum of the diagonal elements. The matrix  $A^* = (\bar{a}_{j,i})$  is the conjugate transpose of  $A = (a_{i,j})$  with conjugation

$$\overline{\sum_{g \in G} c_g g} = \sum_{g \in G} \bar{c}_g g^{-1}.$$

Let

$$F = \begin{pmatrix} \frac{\partial r_1}{\partial x_1} & \cdots & \frac{\partial r_1}{\partial x_g} \\ \vdots & \ddots & \vdots \\ \frac{\partial r_{g-1}}{\partial x_1} & \cdots & \frac{\partial r_{g-1}}{\partial x_g} \end{pmatrix}$$

be the Fox Jacobian (e.g. [BZ85]) of the presentation. We obtain a  $(g-1) \times (g-1)$ -matrix  $A$  by deleting one of the columns of  $F$ .

**Theorem 3.1 (Lück [Lüc02]).** *Suppose the deleted column in the Fox Jacobian does not correspond to a generator  $x_i$  of  $G$  that represents a trivial element in  $G$ . Then for a hyperbolic knot  $K$  and for  $k$  sufficiently large it holds:*

$$\frac{1}{3\pi} \text{Vol}(S^3 - K) = 2(g-1) \ln(k) - \sum_{n=1}^{\infty} \frac{1}{n} \text{tr}_{\mathbb{C}G}((1 - k^{-2}AA^*)^n) \quad (4)$$

The value of  $k$  can be chosen to be the product of  $(g-1)^2$  and the maximum of the 1-norm of the entries in  $A$  (see [Lüc94]).

In case of a non-hyperbolic knot, the right-hand side of (4) is proportional to the Gromov norm of the knot complement.

In the abelian case Theorem 1.1 generalizes to:

**Theorem 3.2 ([Lüc02], see also [Den06]).** *Let  $A$  have entries in  $\mathbb{C}[x_1, \dots, x_r]$ . Then the right-hand side of (4) equals:*

$$2m(\det(A)),$$

where, again,  $m(p) = \int_0^1 \dots \int_0^1 \ln |p(e^{2\pi i t_1}, \dots, e^{2\pi i t_r})| dt_1 \cdots dt_r$  is the (logarithmic) Mahler measure of the polynomial  $p(x_1, \dots, x_r)$ .

**Remark 3.3.** *Let  $K = T(p, q)$  be the  $(p, q)$ -torus knot. It is well-known (e.g. [BZ85]) that a presentation for the knot group of  $T(p, q)$  is given by:*

$$G = \pi_1(S^3 - T(p, q)) = \langle a, b | a^p = b^q \rangle.$$

Hence, the Fox Jacobian for  $G$  is

$$F = (1 + a + a^2 + \cdots + a^{p-1}, -1 - b - \cdots - b^{q-1})$$

and we can chose  $A$  to be the  $1 \times 1$  matrix:

$$A = (1 + a + \cdots + a^{p-1}) \quad \text{and thus} \quad A^* = (1 + a^{-1} + \cdots + a^{-p+1}).$$

Theorems 3.1 and 3.2 now express the fact that the Gromov norm of the torus knot complements is 0.

### 3.1 Covering spaces

For a given knot the terms in Lück's formula (4) are by no means simple to compute. A single term depends on the chosen presentation. Furthermore, the convergence of the series is slow. An indirect approach via covering spaces of the knot complement gives more flexibility for computational simplifications. We illustrate it on the example  $K$  being the trefoil knot. It is well-known that the fundamental group of its knot complement is isomorphic to the braid group  $B_3$  on three strands:

$$B_3 = \langle \sigma_1, \sigma_2 \mid \sigma_1 \sigma_2 \sigma_1 = \sigma_2 \sigma_1 \sigma_2 \rangle.$$

A direct application of Formula (4) to this presentation would lead to a somewhat messy series. However, the group  $B_3$  has a natural homomorphic image in the symmetric group  $S_3$  and its kernel is the pure braid group  $P_3$  of index 6 in  $B_3$ . By an application of Newworld's lemma [DM01]  $P_3$  is isomorphic to the direct product of its center  $C_3 \cong \mathbb{Z}$  and a free group of rank 2. More precisely:

With  $t = (\sigma_1 \sigma_2)^3$  and  $a = \sigma_1^2, b = \sigma_2^2$  a presentation for  $P_3$  is given by

$$P_3 = \langle t, a, b \mid ta = at, tb = bt \rangle.$$

Thus, by deleting the column corresponding to  $t$  from the Fox Jacobian, the reduced matrix  $A$  is:

$$A = \begin{pmatrix} t-1 & 0 \\ 0 & t-1 \end{pmatrix}.$$

By Theorem 1.1 the right-hand-side of Lück's formula (4) equals the logarithmic Mahler measure of  $\det(A) = (t-1)^2$ , which is 0.

Now, since  $P_3$  has index 6 in  $S^3 - K$ , for  $K$  the trefoil, we know [Lüc02] that Formula (4) applied to the complement of the trefoil must be  $\frac{1}{6}$  of this and thus also 0.
